# **Python For Data Science** *Cheat Sheet*

## **Pandas Basics**

Learn Python for Data Science Interactively at www.DataCamp.com

#### **Pandas**

The **Pandas** library is built on NumPy and provides easy-to-use data structures and data analysis tools for the Python programming language.

Use the following import convention:

>>> import pandas as pd

#### Pandas Data Structures

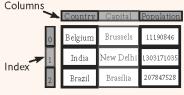

#### Series

A one-dimensional labeled array capable of holding any data type

>>> s = pd.Series([3, -5, 7, 4], index=['a', 'b', 'c', 'd'])

#### DataFrame

A two-dimensional labeled data structure with columns of potentially different types

```
>>> data = {'Country': ['Belgium', 'India', 'Brazil'],
           'Capital': ['Brussels', 'New Delhi', 'Brasília'],
           'Population': [11190846, 1303171035, 207847528]}
>>> df = pd.DataFrame(data,
```

columns=['Country', 'Capital', 'Population'])

## **Asking For Help**

>>> help(pd.Series.loc)

# Selection

#### Getting

```
>>> s['b']
 - 5
>>> df[1:1
   Country
            Capital Population
 1 India New Delhi 1303171035
 2 Brazil Brasília 207847528
```

Get one element

column

column labels

Get subset of a DataFrame

Select single value by row &

Select single value by row &

Also see NumPy Arrays

## Selecting, Boolean Indexing & Setting

#### **By Position**

```
>>> df.iloc[[0],[0]]
 'Belaium'
>>> df.iat([0],[0])
 'Belgium'
```

#### By Label

	>>> df.loc[[0], ['Country']
	'Belgium'
	>>> df.at([0], ['Country'])
	'Belgium'

### By Label/Position

2, 2000, 00,000	
>>> df.ix[2]	Select single row of
Country Brazil	subset of rows
Capital Brasília Population 207847528	
>>> df.ix[:,'Capital']	Select a single column of
0 Brussels	subset of columns
1 New Delhi	
2 Brasília	
>>> df.ix[1,'Capital']	Select rows and columns
'New Delhi'	

## **Boolean Indexing**

>>>	S[~(S > 1)]
>>>	s[(s < -1)   (s > 2)]
>>>	df[df['Population']>12

df['Population']>1200000000]

Setting >>> s['a'] = 6

Set index a of Series s to 6

Series s where value is not >1

Use filter to adjust DataFrame

s where value is <-1 or >2

## 1/0

#### Read and Write to CSV

```
>>> pd.read csv('file.csv', header=None, nrows=5)
>>> df.to csv('myDataFrame.csv')
```

#### Read and Write to Excel

```
>>> pd.read excel('file.xlsx')
>>> pd.to excel('dir/myDataFrame.xlsx', sheet name='Sheet1';
```

### Read multiple sheets from the same file

```
>>> xlsx = pd.ExcelFile('file.xls')
>>> df = pd.read excel(xlsx, 'Sheet1')
```

## Read and Write to SQL Query or Database Table

```
>>> from sqlalchemy import create engine
>>> engine = create engine('sqlite:///:memory:')
>>> pd.read sql("SELECT * FROM my_table;", engine)
>>> pd.read sql table('my table', engine)
>>> pd.read sql query("SELECT * FROM my table;", engine)
```

read sql()is a convenience wrapper around read sql table() and read sql query()

>>> pd.to sql('myDf', engine)

## Dropping

>>> s.drop(['a', 'c'])	Drop values from rows (axis=0)
>>> df.drop('Country', axis=1)	Drop values from columns(axis=1)

## Sort & Rank

```
Sort by labels along an axis
Sort by the values along an axis
>>> df.sort index()
>>> df.sort values(bv='Country'
                                               Assign ranks to entries
>>> df.rank()
```

## Retrieving Series/DataFrame Information

#### **Basic Information**

>>> df.shape >>> df.index	(rows,columns) Describe index
>>> df.columns	Describe DataFrame columns
>>> df.info() >>> df.count()	Info on DataFrame Number of non-NA values

#### Summary

>>> df.cumsum() >>> df.min()/df.max() >>> df.dxmin()/df.idxmax() >>> df.describe() >>> df.mean()	Sum of values Cummulative sum of values Minimum/maximum values Minimum/Maximum index value Summary statistics Mean of values Median of values
--	---

## Applying Functions

>>> f = lambda x: x*2 >>> df.apply(f) >>> df.applymap(f)	Apply function Apply function element-wise
--	---

## **Data Alignment**

### Internal Data Alignment

NA values are introduced in the indices that don't overlap:

```
>>> s3 = pd.Series([7, -2, 3], index=['a', 'c', 'd'])
>>> s + s3
 b
       NaN
       5.0
 C
```

### Arithmetic Operations with Fill Methods

You can also do the internal data alignment yourself with the help of the fill methods:

```
>>> s.add(s3, fill value=0)
 a 10.0
 b
     -5.0
    5.0
>>> s.sub(s3, fill value=2)
>>> s.div(s3, fill value=4)
>>> s.mul(s3, fill value=3)
```

# **Data Wrangling**

with pandas **Cheat Sheet** http://pandas.pydata.org

## **Syntax** – Creating DataFrames

	1	4	7	10	
	2	5	8	11	
	3	6	9	12	
= pd	.DataF	rame(	<i>1</i> F	<i>c</i> 1	

```
df
          {"a" : [4 ,5, 6],
           "b" : [7, 8, 9],
           "c" : [10, 11, 12]},
        index = [1, 2, 3])
```

Specify values for each column.

```
df = pd.DataFrame(
     [[4, 7, 10],
      [5, 8, 11],
      [6, 9, 12]],
     index=[1, 2, 3],
     columns=['a', 'b', 'c'])
Specify values for each row.
```

			а	b	С
	n	v			
	d	1	4	7	10
		2	5	8	11
	e	2	6	9	12

df = pd.DataFrame( {"a" : [4 ,5, 6], "b" : [7, 8, 9], "c" : [10, 11, 12]}, index = pd.MultiIndex.from tuples( [('d',1),('d',2),('e',2)], names=['n','v'])) Create DataFrame with a MultiIndex

# **Method Chaining**

Most pandas methods return a DataFrame so that another pandas method can be applied to the result. This improves readability of code.

df = (pd.melt(df) .rename(columns={

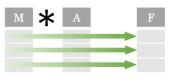

## Tidy Data – A foundation for wrangling in pandas

In a tidy data set:

Tidy data complements pandas's vectorized operations, pandas will automatically preserve observations as you manipulate variables. No other format works as intuitively with pandas.

 $M * \Delta$ 

Each variable is saved in its own column

Each **observation** is saved in its own row

## **Reshaping Data** – Change the layout of a data set

- df.sort values('mpg')
- Order rows by values of a column (low to high).
- df.sort values('mpg',ascending=False) Order rows by values of a column (high to low).
- df.rename(columns = {'y':'year'}) Rename the columns of a DataFrame
- df.sort index()
- Sort the index of a DataFrame
- df.reset index()

Reset index of DataFrame to row numbers, moving index to columns.

df.drop(columns=['Length', 'Height']) Drop columns from DataFrame

# **Subset Observations (Rows)**

Logic in Python (and pandas)

df.column.isin(values)

df[df.Length > 7]

Extract rows that meet logical criteria.

df.drop duplicates() Remove duplicate rows (only considers columns).

df.head(n) Select first n rows.

df.tail(n) Select last n rows.

Less than

Greater than

df.sample(frac=0.5)

Randomly select fraction of rows.

df.sample(n=10)

Randomly select n rows.

df.iloc[10:20]

Select rows by position. df.nlargest(n, 'value')

Select and order top n entries.

df.nsmallest(n, 'value') Select and order bottom n entries.

Not equal to

Group membership

# **Subset Variables** (Columns)

df[['width','length','species']]

Select multiple columns with specific names.

df['width'] or df.width

Select single column with specific name.

df.filter(regex='regex')

Select columns whose name matches regular expression regex.

regex (Regular Expressions) Examples		
'\.'	Matches strings containing a period '.'	
'Length\$'	Matches strings ending with word 'Length'	
'^Sepal'	Matches strings beginning with the word 'Sepal'	
'^x[1-5]\$'	Matches strings beginning with 'x' and ending with 1,2,3,4,5	
'^(?!Species\$).*'	Matches strings except the string 'Species'	

df.loc[:,'x2':'x4']

Select all columns between x2 and x4 (inclusive).
